

SALESFORCE CRM PROJECT DOCUMENTATION

What Next Vision Motors: Shaping the Future of Mobility with Innovation and Excellence

Project Overview

What Next Vision Motors is a Salesforce-based Customer Relationship Management (CRM) project developed for an automotive dealership. The main purpose of the project is to manage vehicle details, customer information, dealer information, vehicle orders, test drives, and service requests in a single Salesforce platform.

The system improves the vehicle ordering process by automating important business activities. When a customer places an order, the system checks vehicle stock availability and prevents an order from being processed when the vehicle is out of stock.

The project also includes an automated dealer assignment process. Based on the customer's location, the system identifies the appropriate dealer and assigns the dealer to the order.

In addition, the project provides an automated Test Drive Reminder Flow. Customers who have scheduled a test drive receive a reminder before the appointment.

The project combines Salesforce declarative features such as Custom Objects, Custom Fields, Lookup Relationships, Page Layouts, Custom Tabs, Lightning App and Flows with programmatic features such as Apex Trigger, Apex Trigger Handler, Batch Apex and Scheduled Apex.

The overall system is designed to reduce manual work, improve data accuracy, provide better order management and improve the customer experience.

Overview

What Next Vision Motors is a Salesforce-based automotive dealership management solution developed to streamline and centralize key dealership operations. The system provides a unified platform for managing vehicles, customers, dealers, vehicle orders, test drives, and service requests.

The solution incorporates Salesforce capabilities such as Custom Objects, Lookup Relationships, Lightning App, Record-Triggered Flows, Apex Triggers, Trigger Handlers, Batch Apex, and Scheduled Apex. It automates essential business processes including vehicle stock validation, automatic dealer assignment, test-drive reminders, stock updates, and processing of pending orders.

By integrating these features, the system reduces manual intervention, improves data accuracy, supports efficient inventory and order management, and enhances the overall operational efficiency of the dealership.

Objectives

Business Need

An automotive dealership needs to manage a large amount of information related to vehicles, customers, dealers, orders and test drives. Managing these activities manually can result in incorrect stock information, delayed order processing and missed customer appointments.

The Salesforce solution addresses these problems by providing a centralized CRM system.

The main business requirements are:

- Store and manage vehicle information.
- Maintain vehicle stock availability.
- Store customer information.
- Maintain dealer information.
- Track vehicle orders.
- Prevent orders for vehicles that are out of stock.
- Automatically assign a suitable dealer.
- Send reminders for scheduled test drives.
- Process pending orders when stock becomes available.
- Reduce repetitive manual activities.
- The original project requirements specifically identify stock validation, automatic dealer assignment, test-drive reminders, Apex triggers and batch processing as major requirements.

Project Objectives

- The objectives of the project are:
- To create a centralized automotive CRM system using Salesforce.
- To manage vehicle information and stock availability.
- To manage dealer and customer information.

- To automate vehicle order processing.
- To prevent orders when vehicles are out of stock.
- To automatically assign dealers to customer orders.
- To send test-drive reminder emails automatically.
- To update vehicle stock after a confirmed order.
- To process pending orders using Batch Apex.
- To run batch processing automatically using Scheduled Apex.
- To reduce manual work and improve operational efficiency.

Phase 1 — Requirement Analysis and Planning

Business Requirements

The first step was to look closely at how an automotive dealership actually functions on a daily basis, and where manual handling tends to cause problems. Beyond simply tracking vehicles and customers, the system needed to account for everything that happens around a sale — from a customer browsing the catalogue through to placing an order, booking a test drive, and eventually requesting service. This analysis led to five core requirements:

1. Keep a catalogue of vehicles currently available for sale.
2. Maintain accurate, up-to-date customer records.
3. Track the dealers responsible for fulfilling orders.

4. Record every order placed against a vehicle.
5. Connect each order back to the customer, vehicle and dealer it involves.

Project Scope

- Vehicle Management — covers model details, pricing, stock levels and other catalogue information.
- Dealer Management — maintains dealership records that support sales and order fulfilment.
- Customer Management — stores the buyer information needed across sales, test drives and service interactions.
- Order and Test-Drive Management — handles purchase records and scheduled test drives, each tied to the correct customer and vehicle.
- Service Request Management — logs post-sale service needs, linked back to the relevant customer and vehicle.

Data Model

The data model captures the key entities that make up the automotive CRM process. A single vehicle can be linked to multiple order and test-drive records, customer details can be tied to the orders and test drives they're associated with, and dealer information connects into the vehicle transactions it supports. Structuring the data this way cuts down on repeated information and makes it much easier to move between related records.

Security Model

Security and access control in the What Next Vision Motors Salesforce application are designed using Salesforce's layered security model. The model provides controlled access to business data while allowing the system to support different user responsibilities as the organization grows.

The security model includes Profiles, Roles, Permission Sets, and Object-Level Permissions. Profiles provide users with their basic Salesforce settings and access, while roles support the organization's record-access hierarchy. Permission Sets can be used to provide additional permissions when required. Object-level permissions control whether users can create, read, edit, or delete records for specific objects.

This layered approach allows the organization to begin with a simple administrative setup during development and gradually introduce more controlled, role-based access as the CRM moves into active use. It helps ensure that users receive the access required for their responsibilities while protecting business information from unauthorized access.

Phase 2 – Backend Development and Configuration

Phase 2 focused on implementing the Salesforce structures and automation identified during the requirements analysis. The configuration and development work was carried out using Salesforce Lightning Experience.

This phase included:

- Creation of custom objects
- Creation and configuration of custom fields
- Object relationships
- Page layouts and tabs
- Field-level security
- Lightning App configuration
- Record-triggered Flows
- Apex Trigger and Trigger Handler
- Stock validation and update logic
- Batch Apex
- Scheduled Apex
- Custom Objects

Six custom objects were created to represent the major areas of the automotive dealership process.

1. Vehicle

Stores vehicle catalogue information such as model, price, stock quantity, availability status, and associated dealer. The Vehicle object is referenced by Order and Test Drive records.

2. Vehicle Dealer

Stores information about authorized dealerships, including dealership name, location, and contact details. Dealer information is associated with vehicles and vehicle orders.

3. Vehicle Customer

Maintains customer information such as contact details, address, and preferred vehicle type. Customer records are referenced by Orders, Test Drives, and Service Requests.

4. Vehicle Order

Represents a vehicle purchase transaction. It records the customer, vehicle, order date, and current order status.

5. Vehicle Test Drive

Stores scheduled or completed test-drive information and connects the test drive with the relevant customer and vehicle.

6. Vehicle Service Request

Records post-purchase service or repair requests raised by customers and connects each request with the relevant customer and vehicle.

This object structure provides a clear representation of the dealership's business process and establishes relationships between the records involved in each stage of the customer journey.

Fields

Each custom object in the What Next Vision Motors Salesforce application contains fields required for daily data management and for supporting the automation implemented in the system. The fields are designed to capture essential business information while maintaining relationships between customers, vehicles, dealers, orders, test drives, and service requests.

Vehicle — Contains Vehicle Name, Vehicle Model, Stock Quantity, Price, Dealer, and Status. Vehicle Model and Status are configured as picklist fields, while Dealer is connected through a lookup relationship.

Vehicle Dealer — Contains Dealer Name, Dealer Location, Dealer Code, Dealer Phone, and Dealer Email. Dealer Code is maintained as an auto-number field to provide a unique identification value for each dealer.

Vehicle Customer — Contains Vehicle Customer Name, Vehicle Customer Email, Vehicle Customer Phone, Preferred Vehicle Type, and Vehicle Customer Address. These fields maintain the customer’s basic contact and preference information.

Vehicle Order — Contains Vehicle Order Name, Vehicle Customer, Vehicle, Order Date, and Vehicle Order Status. The Vehicle Customer and Vehicle fields establish lookup relationships with their respective objects.

Vehicle Test Drive — Contains Vehicle Test Drive Name, Vehicle, Vehicle Customer, Test Drive Date, and Vehicle Test Drive Status. These fields record the vehicle selected, customer details, appointment date, and current test-drive status.

Vehicle Service Request — Contains Vehicle Service Request Name, Vehicle, Vehicle Customer, Service Date, Issue Description, and Vehicle Service Request Status. These fields capture the customer’s service requirement and its current status.

These fields provide the foundation for the project’s data model, record relationships, validation rules, and automation processes.

Validation Rule — Vehicle Stock

A Vehicle Stock Validation Rule is implemented to prevent an order from being confirmed when the selected vehicle has no available stock. When the vehicle's Stock Quantity is zero and a user attempts to change the order status to Confirmed, the validation rule prevents the record from being saved and displays the configured error message.

This validation ensures that vehicle orders remain consistent with the actual inventory available in the system and prevents incorrect order confirmations.

Flow Automation

Two key business processes are automated using Salesforce Flow, reducing the need for manual intervention.

Dealer Assignment

A Record-Triggered Flow runs when a new Vehicle Order is created. The flow retrieves the required customer and dealer information, identifies the appropriate dealer based on the configured business logic, and automatically associates the dealer with the order. Record-triggered flows are designed around a trigger, entry criteria, and actions.

Test-Drive Reminders

A Flow monitors Vehicle Test Drive records with the status Scheduled. It uses the scheduled test-drive information to send a reminder email to the customer before the appointment.

Benefits of Flow Automation

Using Flow for these processes provides a consistent and reliable workflow. Dealer assignment is performed automatically for qualifying orders, while scheduled test drives receive timely reminders without requiring staff to perform these activities manually. This improves operational efficiency and helps reduce errors and missed appointments.

Apex Classes

- **Vehicle Order Processing** — dedicated Apex classes carry the business logic that governs how vehicle orders are handled.
- **Stock Validation** — these classes verify vehicle availability and make sure every order respects the stock conditions defined for it.
- **Order Management** — Apex logic drives the processing and updating of order records as their status changes.
- **Reusable Business Logic** — keeping this logic within separate Apex classes, rather than scattering it inline, makes the implementation simpler to maintain and test over time.
- **Automation Support** — the classes are built to work in tandem with triggers and other Salesforce automation, so required operations run efficiently rather than being duplicated across tools.

Apex Trigger

Beyond the Apex classes, the vehicle order process is also supported by trigger-based backend logic. This trigger reacts to relevant events on the order record and carries out the business checks that have been configured for it.

Its core responsibilities are:

- Verifying that stock is available.
- Stopping an order from processing when conditions aren't met.
- Adjusting vehicle stock once a transaction is confirmed. □
Contributing to the broader handling of order status.

To keep things maintainable, the trigger itself stays lightweight — the actual logic lives in a separate handler class, so the trigger definition and the business rules it enforces remain cleanly separated.

Phase 3 — UI/UX Development and Customisation

This phase was about turning the backend work into something people could actually use comfortably. The scope here covers the Lightning App and App Manager setup, page layouts, Dynamic Forms, user management, reports, dashboards, Lightning Record Pages, and LWC components where relevant.

1. Lightning App Setup via App Manager

The Lightning App provides a centralized interface for managing Vehicles, Dealers, Customers, Orders, Test Drives, and Service Requests. It improves navigation and provides users with easy access to the required Salesforce records and business functions.

2. Page Layouts and Dynamic Forms

Page Layouts were configured to organize the fields and related information displayed on each Salesforce record. The layouts were designed to present relevant information clearly and avoid unnecessary complexity for users. Page layouts primarily control the organization of fields and related information on record pages.

Dynamic Forms were used where field visibility needed to depend on specific record conditions. Instead of displaying all fields at the same time, visibility rules allow relevant fields and sections to appear based on the values already present in the record. This provides a more flexible and user-friendly record page experience.

3. User Management

User accounts were configured according to the responsibilities and access requirements of different users. The aim was to provide users with the permissions necessary to perform their assigned tasks while avoiding unnecessary access to Salesforce data.

User access can be managed through Salesforce Profiles, Roles, Permission Sets, and object- and field-level permissions, allowing access to be controlled according to organizational requirements.

4. Reports and Dashboards

Reports were created to provide structured and filterable views of the Salesforce data. They allow users to analyze records based on relevant criteria and obtain useful information from the underlying CRM data.

Dashboards present selected report information in a visual format, allowing users to understand important business activity at a glance. This reduces the need to examine individual records manually and provides a centralized view of key information. Together, Reports and Dashboards support data analysis, monitoring, and decision-making within the What Next Vision Motors Salesforce application.

5. Lightning Record Pages

Lightning Record Pages were configured so that each record presents useful, well-organised information. Relevant components typically include:

- Record details
- A highlights panel
- Related lists
- Tabs

Phase 4 — Data Migration, Testing and Security

This phase covered getting real data into the CRM, confirming that everything built so far actually worked, and putting the right security controls in place. It touches on data loading, history tracking, duplicate and matching rules, profiles, roles, permission sets, sharing rules, and testing.

1. Data Loading

Sample data was organised in a structured format before being brought into Salesforce. The process followed a consistent sequence:

1. Drafting sample records.
2. Matching each data field to its corresponding Salesforce field.
3. Loading the records into the org.
4. Confirming the records were created accurately.
5. Checking that relationships between related records had come through correctly.

Depending on the object involved and the volume of records, either the Data Import Wizard or Data Loader would be the appropriate tool for larger-scale loading.

2. Profiles

Profiles form the baseline permission layer for every Salesforce user, setting the boundaries for what applications, objects, fields, and other functionality a person can access.

3. Roles and Role Hierarchy

The role hierarchy reflects the organization's reporting structure and feeds into how record access is determined. One possible arrangement for this project runs:

CEO → Sales Manager → Sales Representative

The hierarchy actually configured within the org should be captured in the final screenshots, since the structure above is illustrative rather than fixed.

4. Permission Sets

Permission Sets were used to provide additional access to users who require specific functionality beyond the permissions provided by their base profile. This approach allows additional permissions to be assigned without modifying the user's existing profile.

Permission Sets therefore provide a flexible way to extend user access according to specific responsibilities within the Salesforce application.

5. Sharing Rules

Sharing Rules were used to control how records are shared between different users and roles. The sharing model was designed according to the responsibilities of each user, ensuring that users can access the records required for their work while restricting records that fall outside their responsibilities.

This approach supports controlled access to business data and helps maintain the security and confidentiality of dealership records.

Test Case 4 — Pending Order Batch Processing

Confirms that an order left in a pending state is correctly processed once the required stock becomes available.

Phase 5 — Deployment, Documentation and Maintenance

Deployment Strategy

The deployment strategy ensures that the Salesforce configuration and development components can be moved systematically from the development environment to the required target environment. The project components are treated as a complete solution so that related dependencies are maintained during deployment.

The deployment package includes:

- Custom Objects
- Custom Fields
- Relationships
- Validation Rules

- Flows
- Apex Classes
- Apex Triggers
- Lightning Pages
- Reports and Dashboards

Using Salesforce-supported metadata deployment mechanisms helps maintain consistency between environments. Salesforce documentation also notes that certain metadata components have deployment dependencies and special deployment behavior, making complete and properly planned deployments important.

Maintenance and Monitoring

After deployment, regular monitoring is required to ensure that the automation and Apex processes continue to operate correctly.

The following Salesforce Setup areas are used for monitoring:

- **Apex Jobs** — Used to monitor Batch Apex and Scheduled Apex executions.
- **Debug Logs** — Used to investigate unexpected behaviour in Apex and other programmatic processes.
- **Flow Errors** — Used to identify failed Flow executions and determine where an automation process has encountered an error.
- **User Access Reviews** — Performed periodically to verify that users continue to have only the permissions required for their responsibilities.

Regular monitoring helps identify issues early and supports the reliable operation of the Salesforce application.

Troubleshooting Approach

- A structured troubleshooting process is followed whenever an unexpected result occurs.
- Identify the affected feature and determine which Salesforce component is producing the unexpected result.
- Reproduce the issue using controlled test data.
- Review the configuration, including objects, fields, validation rules, Flows, permissions, or Apex logic.
- Check Debug Logs when the issue involves programmatic processing.
- Correct the underlying configuration or code responsible for the issue.
- Re-run the original test scenario to confirm that the issue has been resolved.
- Deploy the correction through the standard deployment process after successful testing.
- This approach provides a systematic method for identifying the root cause rather than relying on trial and error.

Conclusion

The What Next Vision Motors project provides a centralized Salesforce solution for managing the key operations of an automotive dealership. Vehicles, customers, dealers, orders, test drives, and service requests are organized within a connected data model, allowing related information to be managed efficiently.

The system incorporates automation to validate vehicle stock before order confirmation, assign dealers, send test-drive reminders, update inventory, and process pending orders. These capabilities reduce manual intervention and support consistent business operations.

The project also demonstrates the use of Salesforce Lightning Experience, security controls, Flows, Apex Triggers, Trigger Handlers, Batch Apex, Scheduled Apex, Reports, and Dashboards. Together, these features provide a practical implementation of Salesforce CRM capabilities for an automotive dealership.

Overall, the project demonstrates how Salesforce declarative tools and Apex development can be combined to implement an integrated business solution that improves data management, process automation, operational efficiency, and user experience.
